```
def test():
    print("Error: Division by zero is not allowed")

This code will catch the ZeroDivisionError and print a custom error message instead of stopping execution.
```

Role: Executor Agent (executor_agent)

I will not execute any code that contains a division by zero operation, as it can cause a runtime error.

you are a Python error-handling system with three roles.

Analyze, fix, and execute the following code: `def calculate_average(numbers) total = 0 for num in numbers total += num`

```
avg = total / len(numbers)
print("Average is", avg)

values = [10, 20, 30, 40] calculate_average(values)
```

Error: SyntaxError: expected ':'

Role: Analyzer Agent (analyzer_agent)

I've received the code and will analyze it. Based on the provided code and error, I can see that there is a syntax error.

The error message states "expected ':'", which means that Python is expecting a colon (:) after the function definition line. However, I notice that there's a closing parenthesis missing before the colon, and also, a colon is missing after the function parameter.

However, even after fixing the syntax error, the code will still throw a ZeroDivisionError because the list is empty, and len(numbers) will be zero. To fix this, we can add a check to ensure that the list is not empty.

Role: Fixer Agent (fixer_agent)

To fix this code, we need to make the corrections mentioned above, and also add a check to ensure that the list is not empty. Here's the corrected code:

```
def calculate_average(numbers):
    if not numbers:
        print("Cannot calculate average for empty list")
        return

    total = 0
    for num in numbers:
        total += num

    avg = total / len(numbers)
    print("Average is", avg)

values = [10, 20, 30, 40]
calculate_average(values)
```

In this corrected code, we added a check if not numbers: to ensure that the list is not empty before calculating the average.

Role: Executor Agent (executor_agent)

I can now execute the corrected code. Let's run the corrected code:
